This window presents all syntax and sematic warnings and errors detected by the PSDL Editor. The operator in which the error was detected is indicated under the "Current" column. The "Parent" column indicates the respective parent operator within the PSDL hierarchical operator tree.

From this window, direct access is provided to the operator in which the error was detected or to that operator's parent operator. Prior to accessing the desired operator, the associated error message must be selected. This is accomplished by depressing the left-mouse button with the cursor over the desired error message.

User options:

Close -- Removes the Error Messages popup window.

Goto Parent -- Calls up the parent operator associated with the selected error message.

Goto Current -- Calls up the operator associated with the selected error message.

Help -- This display.

Exceptions:

Unusual behavior of an operator can be flagged through the use of an exception. PSDL facilitates this through the use of the built-in abstract data type of Exception. Exceptions are identified by name. PSDL provides for the raising of an exception of a given name, detecting the presence of an exception with a given name, and determining if no exception was raised (i.e., Normal).

When an exception is raised by an operator, the exception is

transmitted on all data streams of type exception, regardless of the exception stream label, leaving the operator, subject to the stream output guard. The exception is transmitted only over local exception streams. Thus the exception is not transmitted over exception streams which are outputs of another operator. At least one exception output stream should be provided for each operator which is capable of generating an exception.

Popup Window	This window facilitates the entry of an operator's Exception User options through the use of a scrollable text sidest.	Any number of Exceptions can be specified for the selected operator.

return to the Operator Property window.

Help -- This display.

This window facilitates the viewing, entry and modification of an identifier list. The window scrolls up and down for viewing a long lists.

Entry into the list is performed using the Add button. Move to the desired location and press the Add button. A prompt popup window will be provided for the entry of the new identifier. Select OK to accept the identifier and return to the identifier list.

An identifier is modified by selecting (highlighted) the desired identifier and pressing the Edit button. A prompt popup window will be provided similar to that used for adding an identifier. Select OK after correcting the identifier to accept the changes and return to the identifier list. If Edit is depressed without a selected identifier a notice popup window will inform you that nothing was selected to edit.

An identifier is deleted by selecting (highlighted) the desired identifier and pressing the Delete button. The selected identifier will be removed from the list. If Delete is depressed without a selected identifier, a notice popup window will inform you that nothing was selected to delete.

Note that all modifications made to the identifier list are local to the scrollable window until the user accepts the list by depressing OK to return to the parent window. Cancel can be used to abandon all modifications made to the list.

Refer to the "PSDL Grammar" option under the "Help" menu bar for the

syntax of an identifier.

User options:

OR -- Accept the list of identifiers contained in the scrollable vindow and return to the parent window.

Cancel -- Abandon any changes made to the list of identifiers and

-- Abandon any changes made to the list of identifiers an return to the parent window.

-- Provide a prompt popup window for adding an identifier to the list.

-- Remove the identifier which the user has selected

Help

Operator Property Popup Window

This window provides for the viewing and editing of a PSDL operator. All modifications to the operator are local to the Operator Property window until the operator is accepted by selecting UK. Changes can be abandoned by selecting Cancel.

Name: provides a text window from which the user can enter/modify the operator's name. The name must conform to the syntax of a PSDL identifier. The name must all be unique to the current data flow diagram.

Next to the operator's name is a pull down menu for selecting between an operator and a terminator. A terminator has a Maximum Execution Time (WET) of 0.

Implementation Language: provides a pull down menu from which the user may select the desired implementation language.

Trigger: provides for the specification of an operator's trigger control constraint. The syntax for a trigger is given by:

"triggered" [trigger] ["if" expression] [reqmts_trace]

where [trigger] is one of the following:

"by all" id_list "by some" id_list The first control provides for the specification of the [trigger], through the use of a pull down menu. By selecting "By Some" or "By All", a control widget is displayed for entering the Stream 11st.

Selection of the Stream List control will access an ID List popup window from which a list of stream identifiers can be specified.

A popup window can be accessed for specifying the trigger if

condition expression by selecting the "If Condition" control.

Finally, the selection of the "Required By" control access an ID List popup window from which a list of requirement identifiers can be specified.

Timing: Access a pull down menu for selecting the timing characteristics of the operator. By default the operator is "Non-Time Critical". In this state, all additional timing parameters are unavailable. By selecting "Sporadic", the user is provided with the options of Maximum Execution Time (MET), Minimum Calling Period (MCP), and Maximum Response Time (MRT). By selecting "Periodic", the user is provided with the options of MET, Period, and Finish Within.

Each of timing options can be provided with a positive integer along with a time unit, which is available from a pull down menu. The "Required By" control access an ID List popup window from which a list of requirement identifiers can be specified.

The next three controls, "Output Guards", "Exceptions", and "Timer Ops" provide for the specification of operator control constraints.

There is a horizontal line separating the next three controls. Thes controls are used to enter data into the operator's specification.

Refer to the "PSDL Grammar" option under the "Help" menu bar for additional information regarding the syntax of an operator.

User options:

OX -- Accept the operator and return to the main window.

Cancel -- Abandon any changes made to the operator and return

-- Abandon any changes made to the operator and return to the main window.

-- This display.

Help

Operators:

A PSDL operator is a state machine. A state machine contains a finite number of inputs, outputs, and state variables; each of which are represented as a data stream.

When the state machine is executed, it reads one data object from each of the input streams. The output values of the state machine depend solely upon the current values of the input objects that were read and the current value of the state variables. At most, one data object is written to each output stream.

An operator that is implemented using a PSDL supported programming language is referred to as atomic. In this case, the operator's implementation specifies the programming language as well as the another name used to implement the operator. Operators that are not atomic are composite. A composite operator is itself decomposed into a network of operators; communicating through data streams. This stablishes a parent-child relationship between operators. The decomposite operator being the parent and the operators contained in the decomposed network being the children.

Composite operators provide for a hierarchical decomposition of a prototype. At the top most level, the prototype consists of a single operator, referred to as the root operator. Children of the root operator can either be implemented as atomic operators or as composite operators. At the lowest level, all operators are implemented as atomic operators.

In support of real-time prototypes, PSDL provides both time critical

and non-time critical operators. Execution of time critical operators can be triggered either periodically or sporadically (i.e., data driven). In order for the GAPS Execution Support subsystem to obtain a schedule which executes each operator consistently with the timing constraints of the augmented data flow diagram, a bound must be placed on the execution time of the operators. This bound is referred to as the Maximum Execution Time (MET). An operator is time critical if and non-time oritical.

A time critical operator is triggered periodically if it contains a Period (P) timing constraint. Otherwise, the operator is triggered sporadically, based on the arrival of data (i.e., data driven), and must contain a data trigger control constraint.

Since a PSDL prototype represents a closed system, often it is necessary to include operators which are not considered to be part of the prototype to create the closed system. PSDL facilitates the inclusion of these external systems as terminators. Terminators are operators with an assigned MEI of zero, and thus the time required tescute the terminator is not counted against the prototype execution time. The CAPS maintains a simulated real-time clock. During the execution of a terminator, the simulated real-time clock is turned off. Terminators are represented in the PSDL Editor by a rectangular bubble within the data flow diagram. Operators with a non-zero MEI (including those operators with an undefined MEI) are represented in the PSDL Editor by a circular bubble.

This window facilitates the entry of an operator's Dutput guard constraint options through the use of a scrollable text widget.	User options:	
Any number of Unput guards can be specified for the selected operator.	ΟK	Accept the text in the scrollable window and return to the Onerator Property window
The grammar for an Output guard is as follows:	Cancel	Abandon any changes made to the scrollable window and
"output" id_list "if" expression [reqmts_trace]	Help	recum to the uperator Froperty window This display.
Refer to the "PSDL Grammar" option under the "Help" menu bar for		

additional information.

Operator Output Guard Popup Window

Printer Popup Window

This window facilitates the saving of the current data flow diagram as an output image. The image can be saved either to a printer to a file, by selecting either the Printer or the File radio button widgets. If Printer is selected, the user can provide a printer name. If no printer name is supplied, the image is printed on the standard lpr printer. The printer must be capable of accepting PostScript input.

If File is selected, the data flow diagram is saved to the file

specified by the user using the utility xwd. This command produces an X Window System Dump File formatted image. The file name must be provided.

User options:

-- Save the image to either the printer or the user specified file.
-- Return to the main window without saving the image.
-- This display. ĕ

                                                                                                                                                                                                                                                                      time
                                                                                                                                                                                                                                                                                                                  unit
```

Prototype Specification Popup Window

This window is primarily used to view the specification of a PSDL operator. In addition, there are a few constructs of the specification which can only be specified through this window. The remainder of the operator's specification is automatically generated by the background checker.

The input, output, and state list of the operator specification are provided by the background checker. The user is allowed to specify the generic and exception list as well as the maximum execution time.

Refer to the "PSDL Grammar" option under the "Help" menu bar for additional information regarding the syntax of an operator's specification.

User options:

- -- Accept the text in the scrollable window and return to the main window.
 -- Abandon any changes made to the scrollable window and return to the main window.
 -- This display. Cancel OK
- Help.

Stream Property Popup Window

This window provides for the viewing and editing of a data flow diagram stream. Both streams and state streams are supported by this popup window. All modifications to the stream are local to the Stream Property window until the stream is accepted by selecting OK. Changes can be abandoned by selecting Cancel.

Stream Name: provides a text window from which the user can enter/modify the stream's name. The name must conform to the syntax of a PSDL identifier.

Stream Type: provides a text window from which the user can enter/modify the stream's type. The name must conform to the syntax of a PSDL identifier.

State Stream: Yes specifies that the stream is a state stream. No specifies a normal stream.

Selection of state stream access the state stream initial value. Selection of the "State Initial Value" control access a scrollable text window for the specification of the initial value expression. Latency: provides for the entry of a positive integer and a timing unit, through the use of a pull down menu, for specifying the latency in the stream.

Refer to the "PSDL Grammar" option under the "Help" menu bar for additional information regarding the syntax of a stream.

User options:

-- Accept the stream and return to the main window.
-- Abandon any changes made to the stream and return to the main window.
-- This display. Cancel ÖK

Help

TABBET

Streams are used to communicate data objects of a fixed data type from a set of one or more producer operators to a set of one or more consumer operators. While the PSDL syntax and the PSDL Editor represent a stream as a link from one producer to one consumer, multiple producers and multiple consumers are supported by matching stream names (i.e., identifiers) within the stream scope.

PSDL provides two types of data streams: data flow streams and sampled streams. A data flow stream guarantees that no data object is lost or replicated. The data flow stream behaves like a first-in-first-out (FIFO) queue with a langth of one for each consumer. A sampled stream behaves like a single memory cell which contains one data object for each consumer. The most recent data value is obtained each time the stream is read. Thus, data objects may be lost if associated with a fast producer or replicated if associated with a slow producer. The type of data stream used is determined by the consuming operator's trigger control constraint. If the consuming operator contains a "triggered by all" control constraint for a set of streams, those streams are data flow streams. Otherwise, the stream is a sampled stream.

The FIFO queue length of one for a data flow stream restricts the relative execution rates between the producer and consumer operators. In order to guarantee that no data object is lost or replicated, the output rate of the producer must not exceed the execution rate of the consumer for all data flow streams. No such restriction is placed on a sampled stream.

tate Streams:

State streams provide a state machine with memory. State streams are also used to schedule data flow diagrams that would otherwise be impossible to schedule due to circular precedence constraints. A state stream is declared in the specification section of the component in which the state stream first appears in the data flow diagram.

state stream differs from a data stream in that a state stream must

include an initial value. It is the initial value of a state stream which makes it possible for a state stream to break a circular precedence constraint. A state stream is also required when connecting time critical and non-time critical operators.

Stream Consistency:

Within the hierarchical structure of PSDL, a composite operator is implemented as a data flow diagram of a PSDL component at a lower lavel. All inputs to the composite operators in the decomposed data atternal input to at least one of the operators in the decomposed data flow diagram. Likewise, all outputs of the composite operator must be utilized as an external output from at least one of the operators in the decomposed data flow diagram. A similar set of rules require that all external inputs to a decomposed data flow diagram must be inputs to the composite operator and all external outputs to a decomposed data flow diagram must be outputs from the composite operator.

External streams in a decomposed data flow diagram inherit the stream's data object type of the the composite operator. In addition, which type of stream (i.e., data flow stream or sample stream) is derived from the trigger constraint of the consuming operator. For a composite operator, as explained above, an input to a composite operator must also be an input to at least one operator in the decomposed data flow diagram. The trigger constraints of both the composite operator and those of the applicable decomposed operators are used in the derivation of the type.

Stream Data Flow Diagram Representation:

Streams are represented as directed lines within the data flow diagram, with the arrow pointing to the consumer operator. State streams are similarly represented. However, the state stream uses a bold directed line. External streams are missing either a producer or consumer operator. The missing operator is replaced with "External".

This window facilitates the entry of an operator's Timer constraint options through the use of a scrollable text widget. Any number of Timer constraints can be specified for the selected operator.

The grammar for a Timer constraint is as follows:

timer_op id ["if" expression] [reqmts_trace]

Refer to the "PSDL Grammar" option under the "Help" menu bar for

additional information.

User options:

-- Accept the text in the scrollable window and return to the Operator Property window.
-- Abandon any changes made to the scrollable window and return to the Operator Property window.
-- This display. Cancel ŏ

Help

Timers:

PSDL provides timers as predefined abstract state machines. A timer behaves similar to a stopwatch. A timer is modeled as an elapsed time value and a run switch. As long as the run switch is on, the elapsed time value is incremented. Timers have four operations: start, stop, reset, and read. Start turns on the run switch. Stop turns off the run switch and sets the elapsed time value to zero. Read returns the current value of the elapsed time.

Timers are declared in the implementation section of a composite

operator. Timers differ from operators in that they do not appear in the data flow diagram. Timer values (i.e, the result of a read operator) are accessed by referring to the timer by name within the control constraints of an operator.

A timer is visible within the component in which it is declared. If the component's data flow diagram contains a composite operator, then the timer is visible within the decomposed components.

Timers Tool Popup Window

This window facilitates the viewing, entry and modification of a list of timers. The window scrolls up and down for viewing a long list of timers. Timers must conform to the syntax of a PSDL identifier.

desired location and press the Add button. A prompt popup window will be provided for the entry of the new identifier. Select UK to Entry into the list is performed using the Add button. Move to the accept the identifier and return to the identifier list.

identifier and pressing the Edit button. A prompt popup window will OK after correcting the identifier to accept the changes and return to the identifier list. If Edit is depressed without a selected be provided similar to that used for adding an identifier. Select identifier, a notice popup window will inform you that nothing was An identifier is modified by selecting (highlighted) the desired

An identifier is deleted by selecting (highlighted) the desired identifier and pressing the Delete button. The selected identifier will be removed from the list. If Delete is depressed without a selected identifier, a notice popup window will inform you that nothing was selected to delete. Note that all modifications made to the identifier list are local to the scrollable window until the user accepts the list by depressing OK to return to the parent window. Cancel can be used to abandon all modifications made to the list.

Refer to the "PSDL Grammar" option under the "Help" menu bar for the syntax of an identifier.

User options:

Operator Trigger If Condition Popup Window

This window facilitates the entry of an expression for the operator's Trigger control constraint. The syntax for the Trigger control constraint is:

"triggered" [trigger] ["if" expression] [reqmts_trace]

where trigger is defined by one of following:

"by all" id_list "by some" id_list

The "If Condition" button is used to provide the "expression" contained within the "If" term. The id_list of the trigger is specified by first selecting "by all" or "by some" in the Trigger pulldown menu. The id_list is not visible when the Trigger is "unprotected".

Use the scrollable window to specify the expression. Accept the expression by depressing the DK button and return to the Operator Property window.

Refer to the "PSDL Grammar" option under the "Help" menu bar for additional information on the syntax of an "expression".

User options:

-- Accept the text in the scrollable window and return to the Operator Property window.
-- Abandon any changes made to the scrollable window and return to the Operator Property window.
-- This display. š

APPENDIX E. INSTALLATION

The PSDL Editor consists of the background checker and the graph editor.

This appendix describes the process required to compile the graph editor as well as a PSDL Editor driver, used for debugging the graph editor.

1. SOFTWARE REQUIREMENTS

Table XIX contains the software and version numbers used to generate the graph editor. The graph editor was developed on a Sun workstation.

2. COMPILING THE GRAPH EDITOR

Contained within the graph editor source code is the file Makefile, used to build the graph editor. This file is configured to be executed from the graph editor source code directory, which is a subdirectory of a PSDL Editor directory. Prior to generating the graph editor, the user should set the default directory to that which contains the graph editor source code. The graph editor can be generated by simply typing "make" at the Unix prompt. If the graph editor compiles successfully, the image edit_graph will be generated. This file will automatically be located in the parent directory. In addition, the image sde will also be generated, in the parent directory. This is the PSDL Editor driver program, used to test the graph editor in

Table XIX. Support Software

Software	Version
Operating System	SunOS Release 4.1.3
C Compiler	gcc Version 2.6.3
C++ Compiler	g++ Version 2.6.3
Windows	X11 Version 5
	Motif Version 1.1
Make	Sun Version 4.1

Table XX. Graph Editor Required Files

edit_graph	output_guard.hlp
error.hlp	print.hlp
exceptions.hlp	psdl_grammar.hlp
exceptions_list.hlp	spec_tool.hlp
id_list.hlp	stream_property.hlp
inform_tool.hlp	streams.hlp
initial_state.hlp	timer_list.hlp
op_prop_formal_desc.hlp	timers.hlp
op_prop_informal_desc.hlp	timers_tool.hlp
operator_property.hlp	trigger_if_cond.hlp
operators.hlp	types_tool.hlp

a standalone fashion.

Table XX provides a list of the graph editor files required to support the PSDL Editor. The file edit_graph is the image which executes the graph editor. The remainder of the files are help files, which are expected to be located in the directory from which the graph editor is executed.

3. X WINDOW SYSTEM CUSOMIZATION

The PSDL Editor uses Motif to build the graph editor. Consequentially, the X Window System initialization protocol used to define window parameters can be used with the PSDL Editor [Ref. 15]. These parameters can be defined in the file .Xresources-color²⁹, located in your home directory³⁰ Table XXI provides sample declarations to set the default window size for the graph editor as well as for defining the delete key to work like the backspace key.

²⁹Or in the file .Xresources-mono for non-color systems.

³⁰Since this is a "dot" file, it will not appear under the Unix "1s" command. "Dot" files can be seen by using the -a flag (e.g., "1s -a").
